### **Chapter 2. Introduction**

Bashmatic® is a BASH framework, meaning its a collection of BASH functions (500+ of them) that, we hope, make BASH programming easier, more enjoyable, and more importantly, usable due to the focus on providing constant feedback to the user about what is happening, as a script that uses Bashmatic is running.

Bashmatic®'s programming style is heavily influenced by Ruby's DSL languages. If you take a quick look at the is.sh script, it defines a bunch of DSL functions that can be chained with && and || to create a compact and self-documenting code like this:

```
function bashmatic.auto-update() {
  local dir
  dir=${1:-${BASHMATIC_HOME}}
  is.a-directory "${dir}" && {
    file.exists-and-newer-than "${dir}/.last-update" 30 && return 0

    ( cd ${BASHMATIC_HOME} && \
        git.is-it-time-to-update && \
        git.sync-remote )
  }
}

# check if the function is defined and call it is.a-function.invoke bashmatic.auto-update "$@"
```

To use it in your own scripts, you'll want to first study the Examples provided below, and take advantage of ach module available under lib.

Final note, - once Bashmatic is installed and loaded by your shell init files, you can type is.<tab><tab> to see what functions are available to you that start with is. Each module under lib typically defines public functions starting with the name of the file. Such as, functions in array.sh typically start with array.<something>.<action>

Bashmatic® offers a huge range of ever-growing helper functions for running commands, auto-retrying, repeatable, runtime-measuring execution framework with the key function run. There are helpers for every occasion, from drawing boxes, lines, headers, to showing progress bars, getting user input, installing packages, and much more.

A good portion of the helpers within *Bashmatic*® are written for OS-X, although many useful functions will also work under linux. Our entire test suite runs on Ubuntu. There is an effort underway to convert Homebrew-specifc functions to OS-neutral helpers such as package.install that would work equally well on linux.

Start exploring *Bashmatic*® below with our examples section. When you are ready, the complete entire set of pubic functions (nearly 500 of those) can be found in the functions index page.

And, finally, don't worry, **Bashmatic**® is totally open source and free to use and extend. We just like the way it looks with a little ® :)

You can also download the PDF version of this document which is better for print.

- We recently began providing function documentation using a fork of shdoc utility.
   You can find the auto-generated documentation in the USAGE file, or it's PDF version.
- There is also an auto-generated file listing the source of every function and module. You can find it FUNCTIONS.
- Additionally please checkout the CHANGELOG and the LICENSE.

### 2.1. Compatibility

- BASH version 4+
- BASH version 3 (partial compatibility, some functions are disabled)
- ZSH as of recent update, Bashmatic is almost 100% compatible with ZSH.

#### **Not Supported**

• FISH (although you could use Bashmatic via bin/bashmatic script helper, or its executables)

# **Chapter 3. Project Motivation**

This project was born out of a simple realization made by several very senior and highly experienced engineers, that:

- It is often easier to use BASH for writing things like universal installers, a.k.a. setup scripts, uploaders, wrappers for all sorts of functionality, such as NPM, rbenv, installing gems, rubies, using AWS, deploying code, etc.
- BASH function's return values lend themselves nicely to a compact DSL (domain specific language) where multiple functions can be chained by logical AND & and OR || to provide a very compact execution logic. Most importantly, we think that this logic is extremely easy to read and understand.

Despite the above points, it is also generally accepted that:

- A lot of BASH scripts are very poorly written and hard to read and understand.
- It's often difficult to understand what the hell is going on while the script is running, because either its not outputting anything useful, OR it's outputting way too much.
- When BASH errors occur, shit generally hits the fan and someone decides that they should rewrite the 20-line BASH script in C++ or Go, because, well, it's a goddamn BASH script and it ain't working.

Bashmatic's goal is to make BASH programming both fun, consistent, and provide plenty of visible output to the user so that there is no mystery as to what is going on.

# **Chapter 4. Installing Bashmatic**

Perhaps the easiest way to install Bashmatic® is using this boot-strapping script.

### 4.1. Bootstrapping Bashmatic® using curl

First, make sure that you have Curl installed, run which curl to see. Then copy/paste this command into your Terminal.

The shortcut link resolves to the HEAD version of the bin/bashmatic-install script in Bashmatic Repo.

```
bash -c "$(curl -fsSL https://bashmatic.re1.re); \
    bashmatic-install"
```

You can pass additional flags to the bashmatic-install function, including:

- -v or --verbose for displaying additional output, or the opposite:
- -q or --quiet for no output
- -l or --skip-on-login to NOT install the hook that loads Bashmatic on login.
- If you prefer to install Bashmatic in a non-standard location (the default is ~/.bashmatic), you can use the -H PATH flag

For instance, here is a verbose installation with a custom destination:

```
bash -c "$(curl -fsSL https://bashmatic.re1.re); \
bashmatic-install -v -H ~/workspace/bashmatic"
```

Here is the complete list of options accepted by the installer:

```
> bin/bashmatic-install --help
USAGE:
  bin/bashmatic-install [ flags ]
DESCRIPTION:
  Install Bashmatic, and on OSX also installs build tools, brew and latest bash into /usr/local/bin/bash.
  -H, --bashmatic-home PATH
-V, --bash-version VERSION
                                        Install bashmatic into PATH (default: ~/.bashmatic)
                                        Install BASH VERSION (default: 5.1-rc2)
  -P, --bash-prefix PATH
                                        Install BASH into PATH (default: /usr/local)
                                        Do not install Bashmatic Hook into your dotfiles, which
  -l, --skip-on-login
                                        it does by the default. If you skip it, you can always change your mind later and add it to your shell dot files
                                        by running the following on the command line:
                                        You can always do so later with the following: $ ~/.bashmatic/bin/bashmatic load-at-login
                                        This above will install the Bashmatic hook into your shell
                                       dotfile, eg ~/.bash_profile. if you are on BASH, or ~/.zshrc if you are on ZSH..
       --skip-git
--skip-install
                                        Do not abort if the destination has local changes
                                       Only install/verify prerequisites, skip install.
                                       See additional output as bootstrap is running.
        --verbose
                                       See only error output.
Turn on 'set -x' to see all commands running.
        --debug
                                        Show this help message.
```

### 4.2. Understanding what the Installer Does

When you run bash -c "\$(curl -fsSL https://bashmatic.re1.re); bashmatic-install", the following typically happens:

- curl downloads the bin/bashmatic-install script and passes it to the built-in BASH for evaluation.
- Once evaluated, function bashmatic-install is invoked, which actually performs the installation.
  - This is the function that accepts the above listed arguments.
- The script may ask for your password to enable sudo access this may be required on OS-X to install XCode Developer tools (which include git)
- If your version of BASH is 3 or older, the script will download and build from sources version 5+ of BASH, and install it into /usr/local/bin/bash. SUDO may be required for this step.
- On OS-X the script will install Homebrew on OS-X, if not already there.
  - Once Brew is installed, brew packages coreutils and gnu-sed are installed, as both are required and are relied upon by Bashmatic.
- The script will then attempt to git clone the bashmatic repo into the Bashmatic home folder, or if it already exists it will git pull latest changes.
- Finally, unless you specify -l or --skip-on-login the script will check your bash dot files, and will add the hook to load Bashmatic from either ~/.bashrc or ~/.bash\_profile.

The last part my require some explanation.

#### 4.2.1. To load Bashmatic at Login, or Not?

Now, you may or may not want to load Bashmatic on login.

#### If you load Bashmatic on login (the default installer mode):

In other words, you have something like this in your ~/.bashrc:

```
# Let's see if ~/.bashrc mentions Bashmatic:

$ grep bashmatic ~/.bashrc

[[ -f ~/.bashmatic/init.sh ]] && source ~/.bashmatic/init.sh
```

Then you will have insta-access to all of the convenience functions Bashmtic offers (all 700+ of them).

And while loading the init.sh file adds time to your login initialization, and may auto-update the Bashmatic library, there may be good reasons when you prefer NOT to automatically load it on login.

If the above command shows the output you see above, when you grep your bashrc or zshrc, then all Bashmatic Functions will be loaded into your shell. This could be very convenient, for instance,

- you could invoke ruby.install-ruby-with-readline-and-openssl 3.0.1 to get Ruby installed.
- You could invoke gem.remote.version sym to see that the last published verison of sym is 3.0.1.
- You could join an array of values with with array.join ", " apple pear orange

NOTICE: Bashmatic takes no more than 200-300ms to load typically. That said, you might not want to have this many shell functions in your environment, so in that case you can skip login hook by passing -l or --skip-on-login.

#### If you do not want to load Bashnmatic on login

Install it with:

```
bash -c "$(curl -fsSL https://bashmatic.rel.re); bashmatic-install -l"
```

In this case we suggest that you simply add the Bashmatic's bin folder to the \$PATH.

For instance:

```
# ~/.bashrc
export BASHMATIC_HOME="${HOME}/.bashmatic"
export PATH="${BASHMATIC_HOME}/bin:${PATH}"
```

Then you will have access to the executable script bashmatic which can be used \*as a "gateway" to all bashmatic functions:

You use it like so: bashmatic <function> <args>:

Examples below assume you've set the PATH to include \${HOME}/.bashmatic/bin

```
# Eg, if as in the previous example you sourced in Bashmatic:
$ bashmatic.version
2.1.2
# If you have not, you can still invoke 'bashmatic.version':
$ bashmatic version
# Or another function, 'array.join' - if you sourced in init.sh:
$ array.join '|' hello goodbye
hello|goodbye
# Or using the script:
$ bashmatic array.join '|' hello goodbye
hello|goodbye
```

If you get an error, perhaps Bashmatic® did not properly install.

#### 4.2.2. Discovering Available Functions

To discover the breadth of available functions, type the following command to see all imported shell functions:

```
# List all functions using 4-column mode; print top 5 lines
> bashmatic functions 4 | head -5
7z.a
                         db.psql.connect.db-set hl.yellow-on-gray
                                                                                 run.inspect-variables
7z.install
                          db.psql.connect.db-set hr
                                                                                 run.inspect-variables-
                          db.psql.connect.just-d hr.colored db.psql.connect.table- http.servers
                                                                                 run.inspect.set-skip-f
7z.unzip
7z.x
                                                                                 run.on-error.ask-is-en
7z.zip
                          db.psql.connect.table- https.servers
                                                                                 run.print-command
$ bashmatic functions 1 | wc -l
```

### 4.3. Manual Installation

To install Bashmatic manually, follow these steps (feel free to change BASHMATIC\_HOME if you like):

### 4.4. Using Git

```
export BASHMATIC_HOME="${HOME}/.bashmatic"
test -d "${BASHMATIC_HOME}" || \
   git clone https://github.com/kigster/bashmatic.git "${BASHMATIC_HOME}"
cd "${BASHMATIC_HOME}" && ./bin/bashmatic-install -v
cd ->/dev/null
```

### 4.5. Using Curl

Sometimes you may not be able to use git (I have seen issues ranging from local certificate mismatch to old versions of git, and more), but maybe able to download with curl. In that case, you can lookup the latest tag (substitute "v1.6.0" below with that tag), and then issue this command:

```
export BASHMATIC_TAG="v1.13.0"
set -e
cd ${HOME}
curl --insecure -fSsl \
   https://codeload.github.com/kigster/bashmatic/tar.gz/${BASHMATIC_TAG} \
   -o bashmatic.tar.gz
rm -rf .bashmatic && tar xvzf bashmatic.tar.gz && mv bashmatic-${BASHMATIC_TAG} .bashmatic
source ~/.bashmatic/init.sh
cd ${HOME}/.bashmatic && ./bin/bashmatic-install -v
cd ~ >/dev/null
```

### 4.6. Reloading Bashmatic

You can always reload *Bashmatic*® with bashmatic.reload function. This simply performs the sourcing of \${BASHMATIC\_HOME}/init.sh.

### 4.7. Loading Bashmatic at Startup

When you install Bashmatic it automatically adds a hook to your ~/.bash\_profile, but if you are on ZSH you may need to add it manually (for now).

Add the following to your ~/.zshrc file:

```
[[ -f ~/.bashmatic/init.sh ]] && source ~/.bashmatic/init.sh
```

The entire library takes less than 300ms to load on ZSH and a recent MacBook Pro.

# Chapter 5. Discovering via the Makefile

The top-level Makefile is mostly provided as a convenience as it encapsulates some common tasks used in development by Bashmatic Author(s), as well as others useful to anyone exploring Bashmatic.

You can run make help and read the available targets:

```
> make help
docker-build
                     Builds the Docker image with the tooling inside
                    Drops you into a BASH session with Bashmatic Loaded
docker-run-bash
                     Drops you into a FISH session with Bashmatic Loaded
docker-run-fish
                    Drops you into a ZSH session with Bashmatic Loaded
docker-run-zsh
                    Drops you into a BASH session
docker-run
file-stats-git
                     Print all files known to `git ls-files` command
file-stats-local
                    Print all non-test files and run `file` utility on them.
                     Prints help message auto-generated from the comments.
install
                     install BashMatic Locally in ~/.bashmatic
open-readme
                     Open README.pdf in the system viewer
release
                     Make a new release named after the latest tag
setup
                     Run the comprehensive development setup on this machine
                    Lists every single checked in SHELL file in this repo
Tag this commit with .version and push to remote
shell-files
tag
test-parallel
                     Run the fully auto-g mated test suite
                    Run fully automated test suite based on Bats
Auto-generate the doc/CHANGELOG (requires GITHUB_TOKEN env var set)
test
update-changelog
update-functions
                     Auto-generate doc/FUNCTIONS index at doc/FUNCTIONS.adoc/pdf
update-readme
                     Re-generate the PDF version of the README
                     Auto-generate doc/USAGE documentation from lib shell files, to doc/USAGE.adoc/pdf
update-usage
update
                     Runs all of the updates, add locally modiofied files to git.
```

I've added whitespaces around a set of common tasks you might find useful.

Let's take a quick look at what's available here.

### 5.1. Befriending the Makefile

Makefile is provided as a convenience for running most common tasks and to simplify running some more complex tasks that require remembering many arguments, such as make setup. You might want to use the Makefile for several reasons:

1. make open-readme

This tasks opens the PDF version of the README in your PDF system viewer.

2. make install

This allows you to install the Bashmatic Framework locally. It simply runs bin/bashmatic-install script. At most this will add hooks to your shell init files so that Bashmatic is loaded at login.

3. make setup

This task invokes the bin/dev-setup script under the hood, so that you can setup your local computer developer setup for software development.

Now, this script offers a very rich CLI interface, so you can either run the script directly and have a fine-grained control over what it's doing, or you can run it with default flags via this make target.

This particular make target runs bin/dev-setup script with the following actions:

```
dev, cpp, fonts, gnu, go, java, js, load-balancing, postgres, ruby
```

- 4. make test and make test-parallel are both meant for Bashmatic Developers and contributors. Please see the Contributing section on how to run and what to expect from the UNIT tests.
- 5. make update is the task that should be run by library contributors after they've made their their changes and want the auto-generated documentation to reflect the new functions added and so on and so force. This tasks also generates the function index, re-generate the latest PDFs of README, USAGE or the CHANGELOG files.

Running make update is is required for submitting any pull request.

### **5.2. Docker Make Targets**

Bashmatic comes with a Dockerfile that can be used to run tests or jsut manually validate various functionality under linux, and possibly to experiment.

Run make docker-build to create an docker image bashmatic:latest.

Run make docker-run-bash (or ···-zsh or ···-fish) to start a container with your favorite shell, and then validate if your functions work as expected.

Note how this dropped me straight into the Linux environment prompt with Bashmatic already installed.

### **Chapter 6. Examples of Bashmatic in Action**

Why do we need another BASH framework?

BASH is know to be too verbose and unreliable. We beg to differ. This is why we wanted to start this README with a couple of examples.

### 6.1. Example I. Install Gems via Homebrew

Just look at this tiny, five-line script:

```
#!/usr/bin/env bash
source ${BASHMATIC_HOME}/init.sh
h2 "Installing ruby gem sym and brew package curl..." \
    "Please standby..."

gem.install "sym" && brew.install.package "curl" && \
    success "installed sym ruby gem, version $(gem.version sym)"
```

Results in this detailed and, let's be honest, gorgeous ASCII output:

```
Installing ruby gem sym and brew package curl...

Please standby...

installing sym (latest)...

> gem install sym (latest)...

| 2354 ms | 0 |
| 520 ms | 0 |
| checking if package curl is already installed...
```

Tell me you are not at all excited to start writing complex installation flows in BASH right away?

Not only you get pretty output, but you can each executed command, it's exit status, whether it's been successful (green/red), as well each command's bloody duration in milliseconds. What's not to like?!?

Still not convinced?

Take a look at a more comprehensive example next.

### **6.2. Example II: Download and install binaries.**

In this example, we'll download and install binaries kubectl and minikube binaries into /usr/local/bin

We provided an example script in examples/k8s-installer.sh. Please click and take a look at the source.

Here is the output of running this script:

Why do we think this type of installer is pretty awesome, compared to a silent but deadly shell script that "Jim-in-the-corner" wrote and now nobody understands?

#### Because:

- 1. The script goes out of its way to over-communicate what it does to the user.
- 2. It allows and reminds about a clean getaway (Ctrl-C)
- 3. It shares the exact command it runs and its timings so that you can eyeball issues like network congestions or network addresses, etc.
- 4. It shows in green exit code '0' of each command. Should any of the commands fail, you'll see it in red.
- 5. It's source code is terse, explicit, and easy to read. There is no magic. Just BASH functions.
  - If you need to create a BASH installer, Bashmatic® offers some incredible time savers.

Let's get back to the Earth, and talk about how to install Bashmatic, and how to use it in more detail right after.

### **6.3. Example III: Developer Environment Bootstrap Script**

This final and most feature-rich example is not just an example – it's a working functioning tool that can be used to install a bunch of developer dependencies on your Apple Laptop.

the script relies on Homebrew behind the scenes, and therefore would not work on linux or Windows (unless Brew gets ported there).

It's located in bin/dev-setup and has many CLI flags:

```
Bashmatic Mac-OSX DevSetup Installer Version 0.3.0
                                  dev-setup [ flags ]
                                  Installs various packages via Homebrew.
                                                                    Installs everything
Installs dev + specified groups of packages and casks.
Can be space separated array, eg -g 'ruby js monitoring'
Note that dev group is always installed, unless --no-dev.
Skips dev when used with -g flag.
        -a / --all
        -g / --groups
       -d / --no-dev
                                                                    Skip executing group callbacks when installing Skip main installers, and only run the callbacks.
        -c / --only-callbacks
       -r / --ruby-version VERSION
-p / --pg-version VERSION
        -r / --ruby-version VERSION
-p / --pg-version VERSION
-m / --mysql-version VERSION

Ruby version, overrides defaulkt
PostgreSQL version, overrides
MySQL version, overrides
                                                                    Print extra debugging info
Abort if an error occurs. Default is to keep going.
Only print commands, but do not run them
Do not print as much output.
        -v / --verbose
       -e / --exit-on-error
-n / --dry-run
-q / --quiet
GROUPS:
                                                                    bazel, caching, cpp, dev, fonts
gnu, go, java, js, load-balancing, monitoring
mysql, postgres, python, ruby
       This script installs groups of Brew packages and Casks, organized by a programming language or a stack. Each group may register some of its members as Brew services to be started (such as PostgreSQL and MySQL).
       Additionally, each group may optionally register a shell function to run as a callback at the end. For instance, Ruby's callback might be to run bundle install if the Gemfile file is found.
        You can disable running of callbacks with -C / --no-callbacks flag.
EXAMPLES
       \# Installs the following packages, and ruby 2.7.1 with PostgreSQL version 10 ) dev-setup -g 'dev caching fonts gnu js postgres ruby' -r 2.7.1 -p 10
       # Dry run to see what would be installed
> dev-setup -n -g 'cpp gnu fonts load-balancing'
```

In the example below we'll use dev-setup script to install the following:

- Dev Tools
- PostgreSQL
- Redis
- Memcached
- Ruby 2.7.1
- NodeJS/NPM/Yarn

Despite that this is a long list, we can install it all in one command.

We'll run this from a folder where our application is installed, because then the Ruby Version will be auto-

detected from our .ruby-version file, and in addition to installing all the dependencies the script will also run bundle install and npm install (or yarn install). Not bad, huh?

```
${BASHMATIC_HOME}/bin/dev-setup \
  -g "ruby postgres mysql caching js monitoring" \
  -r $(cat .ruby-version) \
  -p 9.5 \ # use PostgreSQL version 9.5
  -m 5.6 # use MySQL version 5.6
```

This compact command line installs a ton of things, but don't take our word for it - run it yourself. Or, at the very least enjoy this one extremely long screenshot:)

### 6.4. Example IV: Installing GRC Colourify Tool

This is a great tool that colorizes nearly any other tool"s output.

Run it like so:

```
${BASHMATIC_HOME}/bin/install-grc
```

You might need to enter your password for SUDO.

Once it completes, run source  $\sim$ /.bashrc (or whatever shell you use), and type something like 1s -al or netstat -rn or ping 1.1.1.1 and notice how all of the above is nicely colored.

### 6.5. Example V: db Shortcut for Database Utilities & db top

If you are using PostgreSQL, you are in luck! Bashmatic includes numerous helpers for PostreSQL's CLI utility psql.

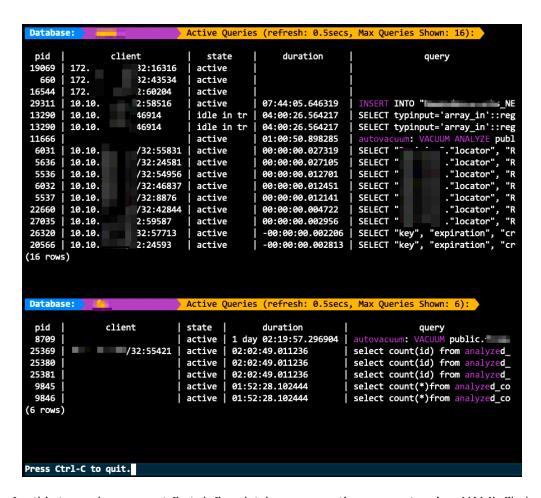

Before you begin, we recommend that you install file .psqlrc from Bashmatic's conf directory into your home folder. While not required, this file sets up your prompt and various macros for PostgreSQL that will come very handy if you use psql with any regularity.

What is db top anyway?

Just like with the regular top you can see the "top" resource-consuming processes running on your local system, with dbtop you can observe a self-refreshing report of the actively running queries on up to **three database servers** at the same time.

Here is the pixelated screenshot of dbtop running against two live databases:

In order for this to work, you must first define database connection parameters in a YAML file located at the following PATH: ~/.db/database.yml.

Here is how the file should be organized (if you ever used Ruby on Rails, the standard config/database.yml file should be fully compatible):

```
development:
   database: development
   username: postgres
   host: localhost
   password:
staging:
   database: staging
   username: postgres
   host: staging.db.example.com
   password:
production:
   database: production
   username: postgres
   host: staging.db.example.com
   password:
production:
   database: production
   username: postgres
   host: production.db.example.com
   password: "a098098safdaf0998ff79789a798a7sdf"
```

Given the above file, you should be able to run the following command to see all available (registered in the above YAML file) connections:

```
$ db connections
development
staging
production
```

Once that's working, you should be able run dbtop:

db top development staging production

At the moment, only the default port 5432 is supported. If you are using an alternative port, and as long as it's shared across the connections you can set the PGPORT environment variable that psql will read.

#### **DB Top Configuration:**

You can configure the following settings for db top:

- 1. You can change the location of the database.yml file with db.confiq.set-file <filepath>
- 2. You can change the refresh rate of the dbtop with eg. db.top.set-refresh 0.5 (in seconds, fractional values allowed). This sets the sleep time between the screen is fully refreshed.

### 6.6. Other db Functions

If you run db without any arguments, or with -h you will see the following:

```
USAGE: db [global flags] command [command flags] connection [— psql flags]

DESCRIPTION: Performs one of many supported actions against PostgreSQL

FLAGS:

-q / —quiet Suppress the colorful header messages
-v / —verbose Show additional output
-n / —dry-run Only print commands, but do not run them

GLOBAL FLAGS:

—commands List all sub-commands to the db script
—connectons List all available database connections
—examples Show script usage examples
—help Show this help screen

SUMMARY:

This tool uses a list of database connections defined in the YAML file that must be installed at: ~/.db/database.yml
```

As you might notice, there is an ever-growing list of "actions" - the sub-commands to the db script.

### 6.7. Sub-Commands of db

You can view the full list by passing -- commands flag:

```
Available Commands

connect
connections
csv
data-dir
db-settings-pretty
db-settings-toml
explain
list-indexes
list-tables
list-users
pga
run
table-settings-set
table-settings-show
top
```

Altgernatively, here is the --examples view:

#### 6.7.1. Sub-Command db connections

You can get a list of all availabled db connections with either

```
db connections
# OR
db --connections
```

### 6.7.2. Sub-Command db pga (eg. pg\_activity)

For instance, a recent addition is the ability to invoke pg\_activity Python-based DB "top", a much more advanced top query monitor for PostgreSQL.

You can invoke db pga <connection> where the connection is taken from the database connection definitions shown above. This is what pg-activity looks like in action:

#### 6.7.3. Other Sub-Commands

Once you know what database you are connecting to, you can then run one of the commands:

#### db connect < connection>

opens psql session to the given connection

#### db db-settings-toml <connection>

prints all PostgreSQL settings (obtained with show all) as a sorted TOML-formatted file.

#### db -q list-tables <connection>

print a list of all tables in the given database, -q (or --quiet) skips printing the header so that only the table listing is printed.

#### db csv <connection> <query>

export the result of the query as a CSV to STDOUT, eg

```
$ db csv filestore "select * from files limit 2"
```

Results in the following output

component\_id,file\_path,fingerprint\_sha\_256,fingerprint\_comment\_stripped\_sha\_256,license\_info 6121f5b3-d68d-479d-9b83-77e9ca07dd2b,weiboSDK/src/main/java/com/sina/weibo/sdk/openapi/models/Tag.java, 6121f5b3-d68d-479d-9b83-77e9ca07dd2b,weiboSDK/src/main/java/com/sina/weibo/sdk/openapi/models/Comment.java,

### 6.8. bin/tablet Script

Building atop of the powerful db script mechanics, is another powerful script called tablet.

The script is meant to be run against one database, and perform a table-level operation on a set of tables that can be specified in numerous ways. It started with the need to ANALYZE only some of the tables, specifically those that have not been auto-analyzed, but grew into a much more capable tool that can do things like:

- Analyze all tables in a database that have never been analyzed`
- Analyze all tables in a database that have not been analyzed in N days
- Analyze a set of specific tables, or exclude tables using regular expression
- Instead of analyzing tables, perform any other table-level command such as:
  - TRUNCATE
  - VACUUM and VACCUUM FULL
  - DROP TABLE
  - REINDEX TABLE
  - etc..

Below is the screenshot of the help screen from this script:

```
> tablet -h
USAGE:
      tablet [options] dbname [table1 table2 ...]
DESCRIPTION:
       Use this script to perform table-level operations in a given database,
      with connection params defined in the file ~/.db/database.yml.
       The default operation is a safe analyze verbose, but can be changed.
      You define db connection either with -d flag, or the first non-flag argument is interpreted as the DB name. Additional non-flag arguments are interpreted as table names, and if provided, used as the tables to perform the action on.
       • To list available database connections. run:
          db --connections
       • To list available db script commands, run:
          db --commands
OPTIONS:
       -d | --database NAME
-o | --operation OPERATION
                                                        Database connection name.
                                                        Operation to perform on a table.
                                                        Defaults to analyze verbose.
      Be very careful with this!
You can use this flag to change 'analyze' to a destructive operation, such as: drop, truncate, vacuum, vacuum full, which may result in an extended application downtime if performed accidentally, or maliciously. Changing the operation forces the interactive confirmation.
                                                       Skip interactive confirmation.

Abort the script if any DB operation fails.

Only print commands to be executed.

Print additional verbose info.
               --yes
--abort-on-error
      -у
-а
              --dry-run
--verbose
--help
       -n
                                                        This help message.
CHOOSING THE TABLES:
       Table specification flags are cumulative: in other words you can combine them.
      Tables obtained by applying the following flags are sorted and uniq'd, and then filtered, whenever a regex filter is provided.
              --table NAME
--since-days DAYS
--unanalyzed
                                                        Operate on a given table(s)
Operate on tables with analyze data older than DAYS
                                                        Operate on tables that have never been analyzed
      Apply additional regex to the list of tables defined by the above options: NOTE: regex can either include (pass) or exclude (reject) table names.
                                                        Regex to apply to include/exclude tables.
EXAMPLES:
      # In the examples below we assume you defined prod.db connection.
# Dry-run — only print what would be analyzed:
tablet —n —d dev.local —t users —t profiles —t sessions
      # analyze all un-analyzed tables, EXCEPT those
# matching 'Locks', '*LDAP*', or 'Pull*'
# note that we define DB conneciton without -d flag here:
      tablet dev.local -u -r '^Locks$|^LDAP|^Pull'
      # vacuum tables matching 'Session*':
tablet dev.local -r '^Session.*$' -o 'vacuum analyze verbose'
```

### **Chapter 7. Usage**

Welcome to **Bashmatic** – an ever growing collection of scripts and mini-bash frameworks for doing all sorts of things quickly and efficiently.

We have adopted the Google Bash Style Guide, and it's recommended that anyone committing to this reported the guides to understand the conventions, gotchas and anti-patterns.

### 7.1. Function Naming Convention Unpacked

Bashmatic® provides a large number of functions, which are all loaded in your current shell. The functions are split into two fundamental groups:

- Functions with names beginning with a . are considered "private" functions, for example .run.env and .run.initializer
- All other functions are considered public.

The following conventions apply to all functions:

- We use the "dot" for separating namespaces, hence git.sync and gem.install.
- Function names should be self-explanatory and easy to read.
- DO NOT abbreviate words.
- All public functions must be written defensively: i.e. if the function is called from the Terminal without
  any arguments, and it requires arguments, the function must print its usage info and a meaningful error
  message.

For instance:

```
$ gem.install

« ERROR » Error - gem name is required as an argument
```

Now let's run it properly:

The naming convention we use is a derivative of Google's Bash StyleGuide, using . to separate BASH function namespaces instead of much more verbose ::.

### 7.2. Seeing All Functions

After running the above, run bashmatic functions function to see all available functions. You can also open the FUNCTIONS.adoc file to see the alphabetized list of all 422 functions.

### 7.3. Seeing Specific Functions

To get a list of module or pattern-specific functions installed by the framework, run the following:

```
$ bashmatic.functions-from pattern [ columns ]
```

For instance:

### 7.4. Various Modules

You can list various modules by listing the lib sub-directory of the \${BASHMATIC\_HOME} folder.

Note how we use Bashmatic® helper columnize [ columns ] to display a long list in five columns.

```
\ \ ls -1 \ BASHMATIC_HOME}/lib | sed 's/\.sh//g' | columnize 5
7z
                   deploy
                                      jemalloc
                                                         runtime-confid
                                                                            time
array
                   dir
                                      json
                                                         runtime
                                                                            trap
                   docker
audio
                                      net
                                                         set
                                                                            url
                   file
aws
                                                                            util
bashmatic
                   ftrace
                                      output
                                                         settings
                   gem
                                      pids
                                                         shell-set
                                                                            vim
                   git-recurse-updat progress-bar
caller
                                                         ssh
                                                                            yaml
                   git
                                                         subshell
                                      rubv
color
                   sedx
                                      run
```

### 7.5. Key Modules Explained

At a high level, the following modules are provided, in order of importance:

### 7.5.1. Runtime Framework — Executing Commands The Right Way™

One of the key parts of Bashmatic is the framework around running commands and reporting on their execution status.

The two most important functions in this framework are:

```
run.set-next [ option option ··· ]run.set-all [ option option ··· ]run "command"
```

The first two allow you to configure how the run command behaves. The run.set-next only affects the first invocation of run. After that all runtime options revert to the defaults.

The following options can be passed to the run.set-next and run.set-all: abort-on-error exits the script when the command fails. ask-on-error interactively asks the user when the command fails. continue-on-error prints a warning, and continues when the command fails. dry-run-on turns dry-run on dry-run-off turns dry-run off on-decline-exit when run.ui.ask is used and user says NO, exits the program. on-decline-return when run.ui.ask is used and user says NO, returns from the function. show-command-on shows the command being executed show-command-off silently executes the command show-output-off swallows command's STDOUT, but prints STDERR on error show-output-on prints STDOUT of the command as it executes

For example:

The following files provide this functionality:

- lib/run.sh
- lib/runtime.sh
- lib/runtime-config.sh.

These collectively offer the following functions:

```
$ bashmatic.functions-from 'run*'
                                                 run.set-next
run.config.detail-is-enabled
                                                 run.set-next.list
run.config.verbose-is-enabled
                                                 run.ui.ask
run.inspect
                                                 run.ui.ask-user-value
run.inspect-variable
                                                 run.ui.get-user-value
run.inspect-variables
                                                 run.ui.press-any-key
run.inspect-variables-that-are
                                                 run.ui.retry-command
run.inspect.set-skip-false-or-blank
                                                 run.variables-ending-with
run.on-error.ask-is-enabled
                                                 run.variables-starting-with
run.print-variable
                                                 run.with.minimum-duration
                                                 run.with.ruby-bundle
run.with.ruby-bundle-and-output
run.print-variables
run.set-all
run.set-all.list
```

Using these functions you can write powerful shell scripts that display each command they run, it's status, duration, and can abort on various conditions. You can ask the user to confirm, and you can show a user message and wait for any key pressed to continue.

#### **Examples of Runtime Framework**

NOTE, in the following examples we assume you installed the library into your project's folder as .bashmatic (a "hidden" folder starting with a dot).

Programming style used in this project lends itself nicely to using a DSL-like approach to shell programming. For example, in order to configure the behavior of the run-time framework (see below) you would run the following command:

```
#!/usr/bin/env bash

# (See below on the location of .bashmatic and ways to install it)
source ${BASHMATIC_HOME}/init.sh

# configure global behavior of all run() invocations
run.set-all abort-on-error show-output-off

run "git clone https://gthub.com/user/rails-repo rails"
run "cd rails"
run "bundle check || bundle install"

# the following configuration only applies to the next invocation of `run()`
# and then resets back to `off`
run.set-next show-output-on
run "bundle exec rspec"
```

And most importantly, you can use our fancy UI drawing routines to communicate with the user, which are based on familiar HTML constructs, such as h1, h2, hr, etc.

#### 7.5.2. Controlling Output

A large chunk of Bashmatic is devoted to printing pretty dialogs and controlling the output of program execution.

The lib/output.sh module does all of the heavy lifting with providing many UI elements, such as frames, boxes, lines, headers, and many more.

Here is the list of functions in this module:

```
$ bashmatic.functions-from output 3
                                                               left-prefix
abort
ascii-clean
                                h.black
box.blue-in-green
                                h.blue
                                                               okay
box.blue-in-yellow
                                                               output.color.off
                                h.areen
box.green-in-cyan
                                                               output.color.on
                                h.red
                                h.yellow
                                                               output.is-pipe
box.green-in-green
box.green-in-magenta
                               h1
                                                               output.is-redirect
box.green-in-yellow
                               h1.blue
                                                               output.is-ssh
box.magenta-in-blue
                                h1.green
                                                               output.is-terminal
box.magenta-in-green
                                h1.purple
                                                               output.is-tty
                                                               puts
box.red-in-magenta
                                h1.red
box.red-in-red
                                h1.yellow
                                                               reset-color
                                                               reset-color:
box.red-in-yellow
                                h2.green
box.yellow-in-blue
                                                               screen-width
box.yellow-in-red
                                h3
                                                               screen.height
box.yellow-in-yellow
                                hdr
                                                               screen.width
                                hl.blue
                                                               shutdown
center
                                hl.desc
                                                               stderr
columnize
                                hl.green
                                                               stdout
command-spacer
                               hl.orange
                                                               success
cursor.at.x
                               hl.subtle
                                                               test-group
                                                               ui.closer.kind-of-ok
cursor.at.y
                               hl.white-on-orange
cursor.down
                               hl.white-on-salmon
                                                               ui.closer.kind-of-ok:
cursor.left
                                hl.yellow
                                                               ui.closer.not-ok
cursor.rewind
                               hl.yellow-on-gray
                                                               ui.closer.not-ok:
cursor.right
                                hr
                                                               ui.closer.ok:
cursor.up
                                hr.colored
                                                               warn
                                inf
                                                               warning
debug
duration
                                info
                                                               warning:
err
                                info:
error
                                left
```

Note that some function names end with: - this indicates that the function outputs a new-line in the end. These functions typically exist together with their non-:-terminated counter-parts. If you use one, eg, inf, you are then supposed to finish the line by providing an additional output call, most commonly it will be one of ok:, ui.closer.not-ok: and ui.closer.kind-of-ok:.

Here is an example:

```
function valid-cask() { sleep 1; return 0; }
function verify-cask() {
  inf "verifying brew cask ${1}...."
  if valid-cask ${1}; then
    ok:
    else
    not-ok:
  fi
}
```

When you run this, you should see something like this:

```
$ verify-cask TextMate

Our verifying brew cask TextMate....
```

In the above example, you see the checkbox appear to the left of the text. In fact, it appears a second after, right as sleep 1 returns. This is because this paradigm is meant for wrapping constructs that might succeed or fail.

If we change the valid-cask function to return a failure:

```
function valid-cask() { sleep 1; return 1; }
```

Then this is what we'd see:

```
$ verify-cask TextMate

U verifying brew cask TextMate....
```

#### **Output Components**

Components are BASH functions that draw something concrete on the screen. For instance, all functions starting with box. are components, as are h1, h2, hr, br and more.

```
$ h1 Hello

Hello
```

These are often named after HTML elements, such as hr, h1, h2, etc.

#### **Output Helpers**

Here is another example where we are deciding whether to print something based on whether the output is a proper terminal (and not a pipe or redirect):

```
output.is-tty && h1 "Yay For Terminals!"
output.has-stdin && echo "We are being piped into..."
```

The above reads more like a high level language like Ruby or Python than Shell. That's because BASH is more powerful than most people think.

There is an example script that demonstrates the capabilities of Bashmatic.

If you ran the script, you should see the output shown in this screenshot. Your colors may vary depending on what color scheme and font you use for your terminal.

#### 7.5.3. Package management: Brew and RubyGems

You can reliably install ruby gems or brew packages with the following syntax:

```
#!/usr/bin/env bash
source ${BASHMATIC_HOME}/init.sh
h2 "Installing ruby gem sym and brew package curl..."
gem.install sym
brew.install.package curl
success "installed Sym version $(gem.version sym)"
```

When you run the above script, you shyould seee the following output:

```
Installing ruby gem sym and brew package curl...

Please standby...

installing sym (latest)...

> gem install sym (latest)...

> gem list > /tmp/.bashnatic/.gem/gem.list.2.7.0p0 (520 ms) 0

checking if package curl is already installed...

« SUCCESS » installed Sym version 2.8.5
```

#### 7.5.4. Shortening URLs and Github Access

You can shorten URLs on the command line using Bitly, but for this to work, you must set the following environment variables in your shell init:

```
export BITLY_LOGIN="<your login>"
export BITLY_API_KEY="<your api key>"
```

Then you can run it like so:

```
$ url.shorten https://raw.githubusercontent.com/kigster/bashmatic/master/bin/install
# http://bit.ly/2IIPNE1
```

#### 7.5.5. Github Access

There are a couple of Github-specific helpers:

```
github.clone github.setup
github.org github.validate
```

#### For instance:

#### 7.5.6. File Helpers

For instance, file.stat offers access to the fstat() C-function:

```
$ file.stat README.md st_size
22799
```

### 7.5.7. Array Helpers

```
$ bashmatic.functions-from array
array.to.bullet-list array.includes
array.has-element array.includes-or-exit
array.to.csv array.from.stdin
array-join array.join
array-piped array.to.piped-list
array.includes-or-complain
```

#### For instance:

```
$ declare -a farm_animals=(chicken duck rooster pig)
$ array.to.bullet-list ${farm_animals[@]}
• chicken
• duck
• rooster
• pig
$ array.includes "duck" "${farm_animals[@]}" && echo Yes || echo No
Yes
$ array.includes "cow" "${farm_animals[@]}" && echo Yes || echo No
No
```

#### 7.5.8. Utilities

The utilities module has the following functions:

```
$ bashmatic.functions-from util
pause.long
                                     util.install-direnv
pause
                                     util.is-a-function
pause.short
                                    util.is-numeric
pause.medium
                                    util.is-variable-defined
pause.medium
util.append-to-init-files
util.arch
util.arch
util.remove-from-init-files
util.call-if-function
util.shell-init-files
shasum.sha-only
                                    util.shell-name
shasum.sha-only-stdin
                                    util.ver-to-i
util.functions-starting-with util.whats-installed
util.generate-password
                                     watch.ls-al
```

For example, version helpers can be very handy in automated version detection, sorting and identifying the latest or the oldest versions:

```
$ util.ver-to-i '12.4.9'
112004009
$ util.i-to-ver $(util.ver-to-i '12.4.9')
12.4.9
```

#### 7.5.9. Ruby and Ruby Gems

Ruby Version Helpers and Ruby Gem Helpers, that can extract curren gem version from either Gemfile.lock or globally installed gem list.

Additional Ruby helpers abound:

```
$ bashmatic.functions-from ruby
bundle.gems-with-c-extensions
                                                ruby.install-ruby-with-deps
interrupted
                                                ruby.install-upgrade-bundler
ruby.bundler-version
                                                ruby.installed-gems
                                                ruby.kigs-gems
ruby.linked-libs
ruby.compiled-with
ruby.default-gems
ruby.full-version
                                                ruby.numeric-version
ruby.gemfile-lock-version ruby.gems
                                                ruby.rbenv
                                                ruby.rubygems-update
ruby.gems.install
                                                ruby.stop
ruby.gems.uninstall
                                                ruby.top-versions
ruby.init
                                                ruby.top-versions-as-yaml
ruby.install
                                                ruby.validate-version
ruby.install-ruby
```

From the obvious ruby.install-ruby <version> to incredibly useful ruby.top-versions <platform> - which, using rbenv and ruby\_build plugin, returns the most recent minor version of each major version upgrade, as well as the YAML version that allows you to pipe the output into your .travis.yml to test against each major version of Ruby, locked to the very latest update in each.

```
$ ruby.top-versions
2.0.0-p648
2.1.10
2.2.10
2.3.8
2.4.9
2.5.7
2.6.5
2.7.0
2.8.0-dev

$ ruby.top-versions jruby
jruby-1.5.6
jruby-1.6.8
jruby-1.6.8
jruby-9.0.5.0
jruby-9.1.17.0
jruby-9.1.17.0
jruby-9.1.17.0
mruby-1.0
mruby-1.0
mruby-1.0
mruby-1.0
mruby-1.2.0
mruby-1.3.0
mruby-1.4.1
mruby-2.0.1
mruby-2.0.1
mruby-2.0.1
mruby-2.0.1
```

#### **Gem Helpers**

These are fun helpers to assist in scripting gem management.

```
$ bashmatic.functions-from gem

g-i gem.gemfile.version
g-u gem.global.latest-version
gem.cache-installed gem.global.versions
gem.cache-refresh gem.install
gem.clear-cache gem.is-installed
gem.configure-cache gem.uninstall
gem.ensure-gem-version gem.version
```

#### For instance

```
$ g-i awesome_print

III gem awesome_print (1.8.0) is already installed
$ gem.version awesome_print
1.8.0
```

#### 7.5.10. Audio & Video Compression Helpers

You can discover the audio and video functions using bashmatic.functions helper:

```
> bashmatic.functions 1 | egrep -i 'video|audio'
audio.dir.mp3-to-wav
audio.dir.rename-karaoke-wavs
audio.dir.rename-wavs
audio.file.frequency
audio.file.mp3-to-wav
audio.make.mp3
audio.make.mp3
audio.make.mp3
svideo-squeeze
video.convert.compress
```

These commands auto-install ffmpeg and other utilities, and then use best in class compression. For instance, here is 80% compressed video file:

```
video-squeeze "2021-01-10 Megan Appeal.m4v"

Compressing "2021-01-10 Megan Appeal.m4v"

Starting ffmpeg conversion, source file size is 334.64 MB

• Source: [2021-01-10 Megan Appeal.m4v]
• Destination: [2021-01-10 Megan Appeal.m4v]
• Algorithm: [411]

Conversion Function: .video.convert.compress-11

Please wait while we compress this file... (set DEBUG-1 to see the output)

> .video.convert.compress-11 "2021-01-10 Megan Appeal.m4v" "2021-01-10 Meg
```

### 7.5.11. Additional Helpers

There are plenty more modules, that help with:

- AWS helpers requires awscli and credentials setup, and offers some helpers to simplify AWS management.
- Docker Helpers assist with docker image building and pushing/pulling
- Sym encryption with the gem called sym

And many more.

See the full function index with the function implementation body in the FUNCTIONS.adoc index.

### **Chapter 8. How To Guide**

### 8.1. Write new DSL in the Bashmatic® Style

The following example is the actual code from a soon to be integrated AWS credentials install script. This code below checks that a user has a local ~/.aws/credentials file needed by the awscli, and in the right INI format. If it doesn't find it, it checks for the access key CSV file in the ~/Downloads folder, and converts that if found. Now, if even that is not found, it prompts the user with instructions on how to generate a new key pair on AWS IAM website, and download it locally, thereby quickly converting and installing it as a proper credentials file. Not bad, for a compact BASH script, right? (of course, you are not seeing all of the involved functions, only the public ones).

```
# define a new function in AWS namespace, related to credentials.
# name of the function is self-explanatory: it validates credentials
# and exits if they are invalid.
aws.credentials.validate-or-exit() {
   aws.credentials.are-valid || {
     aws.credentials.install-if-missing || bashmatic.exit-or-return 1
   }
}

aws.credentials.install-if-missing() {
   aws.credentials.are-present || { # if not present
     aws.access-key.is-present || aws.access-key.download # attempt to download the key
   aws.access-key.is-present && aws.credentials.check-downloads-folder # attempt to find it in ~/Downloads
}

aws.credentials.are-present || { # final check after all attempts to install credentials
     error "Unable to find AWS credentials. Please try again." && bashmatic.exit-or-return 1
}

bashmatic.exit-or-return 0
}
```

Now, how would you use it in a script? Let's say you need a script to upload something to AWS S3. But before you begin, wouldn't it be nice to verify that the credentials exist, and if not – help the user install it? Yes it would.

And that is exactly what the code above does, but it looks like a DSL. because it is a DSL.

This script could be your bin/s3-uploader

```
aws.credentials.validate-or-exit
# if we are here, that means that AWS credentials have been found.
# and we can continue with our script.
```

# 8.2. How can I test if the function was ran as part of a script, or "sourced-in"?

Some bash files exists as libraries to be "sourced in", and others exist as scripts to be run. But users won't always know what is what, and may try to source in a script that should be run, or vice versa - run a script that should be sourced in.

What do you, programmer, do to educate the user about correct usage of your script/library?

Bashmatic® offers a reliable way to test this:

```
#!/usr/bin/env bash
# load library
if [[ -f "${Bashmatic__Init}" ]]; then source "${Bashmatic__Init}"; else source ${BASHMATIC_HOME}/init.sh;
fi
bashmatic.validate-subshell || return 1
```

If you'rather require a library to be sourced in, but not run, use the code as follows:

```
#!/usr/bin/env bash
# load library
if [[ -f "${Bashmatic__Init}" ]]; then source "${Bashmatic__Init}"; else source ${BASHMATIC_HOME}/init.sh;
fi
bashmatic.validate-sourced-in || exit 1
```

### 8.3. How can I change the underscan or overscan for an old monitor?

If you are stuck working on a monitor that does not support switching digit input from TV to PC, NOR does OS-X show the "underscan" slider in the Display Preferences, you may be forced to change the underscan manually. The process is a bit tricky, but we have a helpful script to do that:

```
$ source init.sh
$ change-underscan 5
```

This will reduce underscan by 5% compared to the current value. The total value is 10000, and is stored in the file /var/db/.com.apple.iokit.graphics. The tricky part is determining which of the display entries map to your problem monitor. This is what the script helps with.

Do not forget to restart after the change.

Acknowledgements: the script is an automation of the method offered on this blog post.

# **Chapter 9. Contributing**

Please submit a pull request or at least an issue!

### 9.1. Running Unit Tests

The framework comes with a bunch of automated unit tests based on the fantastic framework bats.

Bats is auto-installed by the bin/specs script.

### 9.1.1. Run Tests Using the Provided bin/specs script

We use Bats framework for testing, however we provided a convenient wrapper bin/specs which installs Bats and its dependencies so that we don't have to worry about installing it manually.

The script can be run:

- 1. Without any arguments to run all tests in the test folder, or
- 2. You can pass one or more existing test file paths as arguments, eg bin/specs test/time\_test.bats
- 3. Finally, you can pass an abbreviated test file name eg "time" will resolve to test/time\_test.bats

The script accepts a bunch of CLI arguments and flags shown below:

```
BASHMATIC TEST RUNNER, VERSION 1.13.0

© 2016-2021 Konstantin Gredeskoul, All Rights Reserved, MIT License.

USAGE

bin/specs [ options ] [ test1 test2 ... ]

where test1 can be a full filename, or a partial, eg. 'test/util_tests.bats' or just 'util'. Multiple arguments are also allowed.

DESCRIPTION

This script should be run from the project's root.

It installs any dependencies it relies on (such as the Bats Testing Framework) seamlessly, and then runs the tests, typically in the test folder.

NOTE: this script can be run not just inside Bashmatic Repo. It works very well when invoked from another project, as long as the bin directory is in the PATH. So make sure to set somewhere:

export PATH=${BASHMATIC_HOME}/bin:${PATH}}

OPTIONS

-p | -parallel Runs all tests in parallel using parallel dependency. This may speed up your test suite by 2-3x

-i | -install METHOD Install Bats using the provided methjod. Supported methods: brew, sources

-c | --continue Continue after a failing test file.

-t | -taps Use taps bats formatter, instead of pretty.

-h | -help Show help message
```

### 9.1.2. Run Tests Sequentially using the Makefile

Alternatively, you can run the entire test suite via the Makefile, using one of two targets:

# Sequential
make test

# Parallel
make test-parallel

### 9.1.3. Running Specs in Parallel with bin/spec -p

One of the very useful flags to bin/specs script is the -p/--parallel.

If you invoke it with this flag, the script will install **GNU Parallel** utility, which is in itself worth reading about. We refer you to the following set of YouTube Introductory Videos on taking advantage of GNU Parallel projects and it's executable.

Below is the screenshot of the tests running with the parallel flag. The script automatically detects that my machine has 16 CPU cores and uses this as a parallization factor.

```
specs -p

/ gem.gemfile.version returns correct 3-part version [0]
 √ git.repo-is-clean() when dirty [0]
   git.repo-is-clean() when clean [0]
   is.a-function.invoke() [0]
```

#### 9.1.4. Run Tests Parallel using the Makefile

Note that you can run all tests in less than 15 seconds by using GNU parallel. Just run the following make target, and it will install any dependencies.

### make test-parallel

While not every single function is tested (far from it), we do try to add tests to the critical ones.

Please see existing tests for the examples.
